This report covers the design and development of automatic test equipment used to evaluate transistor, microcircuit, and hybrid circuit devices undergoing field tests in the Panama Canal Zone. The devices under test are returned annually to the ERADCOM, Electronics Technology & Devices Lab, Fort Monmouth, for data collection and data processing. The test system is computer-controlled. providing automatic device parameter measurement and data manipulation, which include data editing, data printouts, and device performance summaries.

INTRODUCTION

This report describes an automatic test system designed specifically to obtain and process data on transistors, microcircuits, and hybrid microcircuits undergoing field tests at the US Tropic Test Center in the Panama Canal Zone. More than 5000 devices have been returned annually to the Electronics Technology & Devices Laboratory (ET&DL), ERADCOM, for data acquisition since the start of the test program in 1970.

The purpose of the Panama tests is to obtain field life test data on both plastic-encapsulated and hermetically-sealed semiconductor devices when operated in "worst case" temperature and humidity field conditions in jungle and sea shore tropical environments. Field tests are performed near the Caribbean Sea where the air-salt content is very high and in the jungle where the salt content of the atmosphere is very low. Test results are compared with data obtained on similar devices in an autoclave test program at ET&DL. Data correlation is studied to determine acceleration factors, Results of this study have been reported in other technical papers. 1,2,3,4,5

The test system development evolved from an earlier ET&DL design in which an HP9825A Desk-Top Computer was used for data storage and manipulation but did not perform any tester control functions. In a still earlier ET&DL design, data was recorded on punched tape and then transferred to punched cards for batch processing on a Burroughs B5500 Computer. In the present system, parameter measurements, test fixture operation, data storage and manipulation are all controlled by the HP9825A Desk-Top Computer.

SYSTEM DESIGN

The test system measures electrical parameters of transistors, microcircuits, and hybrid circuits. Test instrumentation includes the following: digital multimeter (DMM), digital processor, display station, extended tape memory, printer, desk-top computer, and an in-house-developed test fixture. The measuring and data processing instruments interface using IEEE Standard 488. Computer test programs for the prior ET&DL tester were modified for use with the present test system.

The devices under test are mounted on circuit boards containing either 16 microcircuits, 12 hybrid circuits, or 24 transistors. The test program selects devices sequentially and inserts parameter test circuitry as needed. Display lamps on the test fixture panel are used to track device sequencing.

Parameter measurements for NPN and PNP transistors include I_{CBO} , h_{FE} , and V_{BF} . Microcircuit and hybrid circuit measurements are restricted to digital logic output levels. The microcircuits under test include complementary metal oxide semiconductor (CMOS) NOR Gates, bipolar NAND Gates, and NPN transistor arrays. The hybrid circuits are dual level converters.

The test system is configured as shown in Figure 1. The processor transmits logic signals to the test fixture for device sequencing and test circuit selection. The DMM measures voltage and current parameters and returns test data to the computer for further processing. The display station and extended tape memory are used for editing and storing data summaries. The test system wire list is given in Table 1.

The test fixture (Figure 2) is comprised of a test socket, relay board with display lamps, and a measurement circuit board. Circuit schematics are shown in Figures 3, 4, and 5. The test fixture components are given in Table 2. The test fixture wire list is given in Table 3. Processor control wiring is shown in Figure 6.

TEST SYSTEM OPERATION

Computer programs for the test system are recorded on cassette tape. In the data-taking program, the computer requests information on device type, manufacture, test board number, test bias condition, test hours, and other identifying data. The requested board is then inserted in the test fixture socket for automatic testing.

The processor includes both digital and analog input and output functions. Since the DMM is used to measure electrical parameters, the processor is required only to provide digital output signals for test fixture control. The underutilized processor can be replaced by a HP98032 16 Bit Duplex Interface configured for direct computer control of all relays in the test fixture. A binary output field from the processor controls two decoders on the relay board for relay sequencing of devices under test. Digital logic signals are transmitted to the measurement board relays for sequencing of parameter test circuits.

The DMM is instructed to measure device voltages and transistor leakage currents. This information is transmitted to the computer for further processing, data printout, and data storage. The parameter measurements include: (a) transistor base to emitter voltage V_{BE} , (b) voltage drop measured across a 10 $k\Omega$ resistor in the transistor base circuit for sensing base current, I_B , (c) transistor collector to base leakage current, I_{CBQ} , and (d) voltage levels for digital logic output of microelectronic devices and hybrid circuits. Transistor current gain, h_{FE} , is calculated by the computer using the ratio of collector current (fixed at 2mA) and base current. Pass-fail limits are programmed for each parameter measurement.

Test data may be edited to show failure status, device removal from the test board, or other needed information. Failure is shown as "Possible Failure" and curve-tracer tests are then made for verification. Device failure rates and cumulative test hours are determined using a data summary program. New test data in the extended tape memory is transferred to the display station where it is merged with previous data and a data summary printout obtained.

COMPUTER PROGRAMS

A flow chart of test options is shown in Figure 7. Computer programs for transistor, microcircuit, and hybrid circuit data-taking, and data summaries are given in Appendices A, B, C, D, and E. The data-taking programs developed at ET&DL for the earlier tester were modified for the present system; the data format and summary programs were essentially unchanged. The test programs are not in their most concise form. Since certain routines are repeated for each device category, some test programs can be combined to reduce the software requirement. Examples of test data and data summary printouts are given in Appendices F and G. Other test programs include a "Split Board" routine for test boards containing devices from two different manufacturers (Appendix H), and a "Table of Contents" routine for stored data (Appendix I).

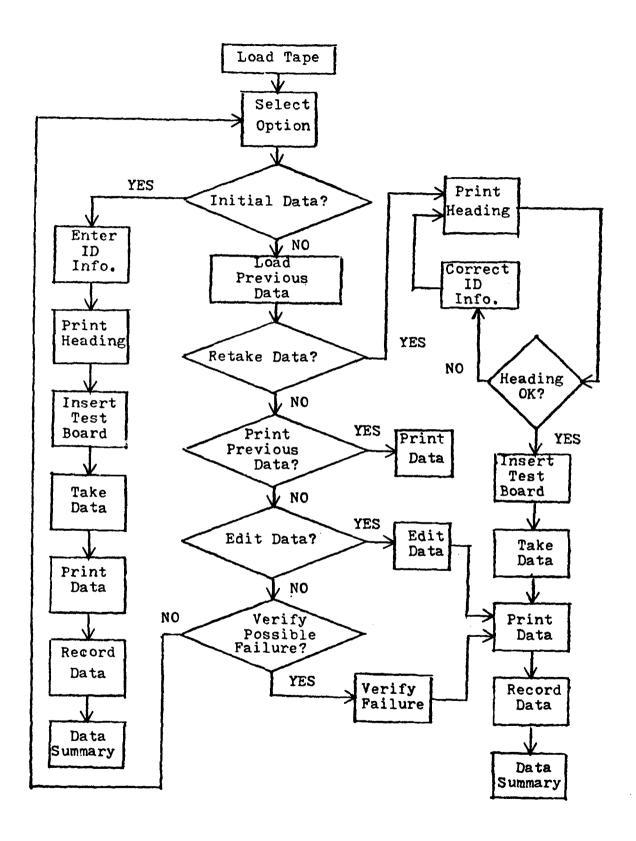

Figure 7. Test Program Flow Chart 14

CONCLUSIONS

The computer-controlled test system is being used successfully to obtain and process test data on transistors, microcircuits, and hybrid circuits undergoing field tests in Panama. Test data and data summaries may be edited and data printouts obtained for each test board. Data summary information provides a useful history of device reliability and test board status.

ACKNOWLEDGEMENTS

Acknowledgement is given to Mr. Robert Sproat and Mr. James Metz of the Microelectronics Division, ET&DL, and to Mr. Gregory Malinowski of the Microwave and Signal Processing Division, ET&DL -- Mr. Sproat for the original data manipulation software, and all present data format, editing, and data summary software, Mr. Malinowski for his development of the original automatic tester, and Mr. Metz for his work on layout and fabrication of printed circuit boards for the test fixture.
